HP 9g Solving Compound Interest Problems

Compound Interest

Practice Solving Compound Interest Problems

Compound interest

Interest is a charge for the use of money. There are two types of interest calculations: simple and compound. With the former, only the original amount of money (i.e. the principal) earns interest for the entire life of the transaction:

$$\text{interest} = \text{principal} \times \text{interest rate} \times \text{time}$$

For example, suppose you put $1,000 in the bank at 6% simple interest for 3 years. You would earn $1,000 × 6% × 3 = $180. In essence, you receive $60 in interest at the end of each year. By *adding the interest* to the principal each year you could earn more money: suppose at the end of the first year, you withdraw the $1,060, go to another bank, and deposit a balance of $1,060. The second year you will earn $1,060 × 6% × 1 = $63.60. You do the same thing again and, at the end of the third year, earn $1,123.60 × 6% × 1 = $67.42. So instead of $180, you receive $191.02. This is the way *compound* interest works: each time the interest is paid, it is added to the balance. Calculations involving compound interest use the following formula:

$$\boxed{F = P(1+i)^n}$$

where *F* is the future value, *P* is the principal, *i* is the interest rate and *n* is the number of compounding periods. Compound interest is usually "compounded" (i.e. paid) annually, but it may also be monthly, quarterly or semiannually.

Even though the HP 9g is a scientific calculator, it can solve a wide variety of compound interest problems. Several examples are shown below.

Practice solving compound interest problems

Example 1: Calculate the future value of $3,000 invested at 7% for 5 years.

Solution: The future value is given by the compound interest formula: $F = 3000 \cdot (1+7\%)^5$. Press:

3Z EXP 3Z (N 1X + 7P 2nd % ▸ 2nd ^ 5U ENTER

Answer: $4,207.66, rounded to the nearest cent.

Example 2: Find the principal which yields $25,000 when invested at 3% annually for 20 years.

Solution: The principal is $P = \dfrac{F}{(1+i)^n} = \dfrac{25000}{(1+3\%)^{20}}$, which can be calculated as follows:

2Y 5U EXP 3Z ÷ (N 1X + 3Z 2nd % ▸ 2nd ^ 2Y 0 ENTER

Answer: The principal that must be invested is $13,841.89.

Example 3: How many time periods are needed to increase $10,000 at 8.5% annual interest to $15,000?

Solution: The unknown value is now n, which is given by: $n = \ln\left(\frac{F}{P}\right) \Big/ \ln(1+i)$. In this example:

$n = \frac{\ln(15000/10000)}{\ln(1+8.5\%)}$. The keystroke sequence is then:

Answer: n = 4.97, so the number of time periods is five.

Example 4: Find the annual interest rate that produces $100,000 from $20,000 in 15 years.

Solution: The formula is now: $i = \left(\frac{F}{P}\right)^{\frac{1}{n}} - 1$, where F = 100000, P = 20000 and n = 15:

Answer: i = 0.1133 or 11.33%.

Example 5: Calculate the effective interest rate compounded quarterly of a 13% annual rate.

Solution: Given the nominal annual rate *i*, the effective interest rate *E* is calculated as follows:

$$E = \left(1 + \frac{i}{n}\right)^{n} - 1$$

where n is the number of compounding periods, i.e. n = 4 in this example. Press:

Answer: E = 0.1365 or 13.65%.

Example 6: Calculate the effective interest rate of a 10% annual rate compounded *continuously*.

Solution: When compounding is continuous, the effective rate is given by:

$$E = e^{i} - 1$$

Therefore the keystroke sequence is:

Answer: E = 0.1052 or 10.52%.
